

## Report: Time Savings and Reproducibility Using Dagster ML Pipeline

Conventional machine learning workflows run in Jupyter notebooks can struggle with reproducibility because of the non-linear execution of cells, modifications of code, and changes made to the versions of data. Often, these problems lead to inconsistent results and hinder effective tracking of experiments. To mitigate these challenges, this project investigates the use of Dagster as a data orchestration framework for building a structured and reproducible machine learning pipeline.

The pipeline was built using the Superstore dataset and goes through all the primary steps of a standard machine learning workflow: data ingestion and preprocessing, model training and evaluation, and visualization of results. Three different types of classification models (Decision Tree, Random Forest, and Logistic Regression) were built and evaluated. Dagster guarantees that there are explicit dependencies established between different stages of the pipeline, which will ensure consistent execution orders and reproducible data flows.

Reproducibility of both runs was demonstrated by running the same pipeline against the original and a modified dataset without changing code in either version of the pipeline. While both runs of the pipelines were tracked by Dagster as different runs, the timing difference between the two pipelines was measurable. While the workflow was executed in a traditional Jupyter Notebook, the original dataset took **2.80 seconds** to execute, while the modified dataset required only **2.33 seconds** to complete; in contrast, the Dagster-based pipeline took **1 minute 14 seconds** for the original dataset and **1 minute 12 seconds** for the modified dataset. While the notebook-based approach was substantially faster for this dataset size than the Dagster-based pipeline, there are clear advantages to using Dagster with respect to execution control, reproducibility, and workflow organization, all of which make it a better fit for machine learning pipelines scaled and deployed into production environments where reliability and traceability are critically important.

## Dagster:

The screenshot shows the Dagster web interface at `127.0.0.1:3000/jobs`. The left sidebar has a dark theme with navigation links: Overview, Runs, Catalog, **Jobs**, Automation, Lineage, Deployment, Search, Hide navigation, Settings, and Support. The main area is titled "Jobs" and contains a search bar and three pipeline definitions under the "superstore\_repo" namespace:

- `superstore_pipeline_modified` (indicated by a blue dot)
- `superstore_pipeline_original` (indicated by a green dot)

## Dagster pipeline (Original Dataset):

The screenshot shows the Dagster Pipeline Overview for `superstore_pipeline_original` at `127.0.0.1:3000/locations/superstore_repo@pipeline.py/jobs/superstore_pipeline_original`. The left sidebar is identical to the previous screenshot. The main area shows the pipeline graph with the following steps:

```
graph TD; A[load_data] --> B[preprocess]; B --> C[eda]; B --> D[split_data]; D --> E[train_models]; E --> F[plot_results]
```

The right panel displays pipeline metadata:

- Job:** superstore\_pipeline\_original
- Description:** No description provided
- Resources:** (empty)
- Metadata:** (empty)
- Tags:** (empty)

Job: superstore\_pipeline\_origin
